

# 10.2 Diffusion and Cellular Automata

# Simulating Motion: Cellular Automata

- If all we have to work with is a grid of cells (spreadsheet), how can we simulate a random walk?
- Moving a value from one cell to an adjacent cell is simulated by changing the contents of the cells over time:

time  $t$

time  $t + 1$

# The Wave

# Aside: The Wave/Particle Duality

- We tend to think of “true” motion as movement of an object from one location to another, and the wave phenomenon as an illusion of motion.
- But at the most fundamental level, energy and matter behave like both a particle (object) *and* a wave....

# Aside: The Wave/Particle Duality

**Double-slit experiment** (Young 1801):  
Light must be a wave, because interference produces more than two bands on screen.

**Photoelectric effect** (Thomson 1899):  
Light must consist of particles, because light waves knock electrons out of a metal plate.

# Cellular Automata

- A **cellular automaton** (plural **automata**) is a dynamical model discrete in space, time, and state (possible values, typically just 0 and 1).
- CA has a grid of cells, and a set of **transition rules** describing what happens to a cell based on its own state and the state of its neighbors.
- Simplest CA are one-dimensional....

# 1D Cellular Automata

Sample rule: Look at a cell and its left and right neighbors. Change the cell according to the following table:

|                           |     |     |     |     |     |     |     |     |
|---------------------------|-----|-----|-----|-----|-----|-----|-----|-----|
| current pattern           | 111 | 110 | 101 | 100 | 011 | 010 | 001 | 000 |
| new state for center cell | 0   | 1   | 1   | 0   | 1   | 1   | 1   | 0   |

# ExCellular Automata

- Each row is the state of the CA at a particular time step.
- First row has random values:  
= IF(RAND()>0.5, 1, 0)
- Subsequent rows have rule:  
=IF( OR (AND( A1=1,B1=1,C1=1),  
AND (A1=1,B1=0,C1=0),  
AND (A1=0,B1=0,C1=0)), 0, 1)

# ExCellular Automata

- Drag second row, second column rightward to next-to-last
- Keep first and last columns (**boundary conditions**) constant
- Drag second row down 60 or 70 rows
- Use Conditional Formatting / Color Scales to color cells based on values
- Zoom out to view whole display
- Hit F9 key to restart with new initial conditions
- Experiment with other rules:

|                           |     |     |     |     |     |     |     |     |
|---------------------------|-----|-----|-----|-----|-----|-----|-----|-----|
| current pattern           | 111 | 110 | 101 | 100 | 011 | 010 | 001 | 000 |
| new state for center cell | 0   | 0   | 0   | 1   | 1   | 1   | 1   | 0   |

# Diffusion: Cellular Automata in Nature

# Diffusion: Cellular Automata in Nature

# 2D Cellular Automata

# Diffusion

- **Diffusion** refers to any process in which a substance or property spreads from one region to another: transfer of heat, spread of dye in a liquid, motion of ants outward from a nest, etc.

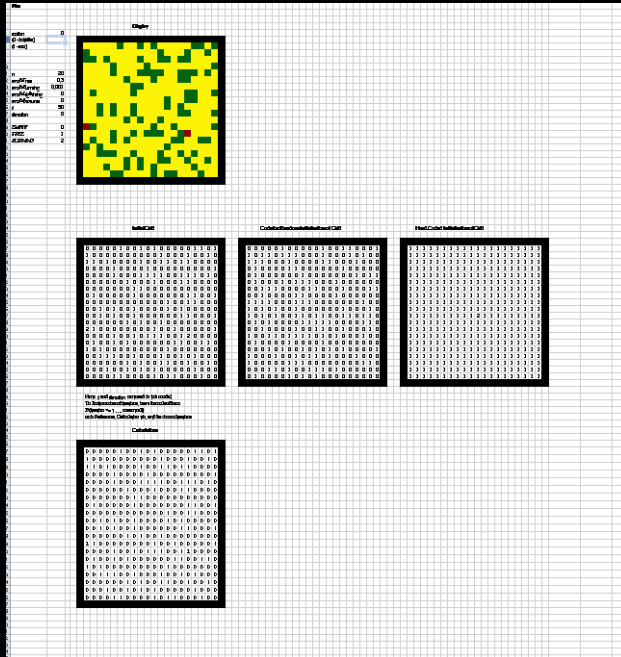

Diffusion has traditionally been modeled using differential equations / systems dynamics – averages over large regions of individuals.

Modern advances in computing power allow us to use cellular automata to model diffusion at the level of individual ants, molecules, etc.

# Diffusion & Cellular Automata

We will study diffusion via cellular automata.

With Excel, this becomes difficult:

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 1 | 0 |
| 1 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 1 | 1 | 1 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 | 0 | 0 | 1 |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 0 | 0 | 0 | 1 | 0 | 0 | 1 |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 0 | 0 | 0 | 0 | 1 | 1 | 0 |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

= IF(action = 0, M54, IF(OR(M24 = EMPTY, M24 = BURNING), EMPTY, IF(OR(M23=BURNING, N24=BURNING, M25=BURNING, L24=BURNING), IF(RAND() < probImmune, TREE, BURNING), IF(RAND() < probLightning\*(1 - probImmune), BURNING, TREE))))))

# Cellular Automata in Matlab

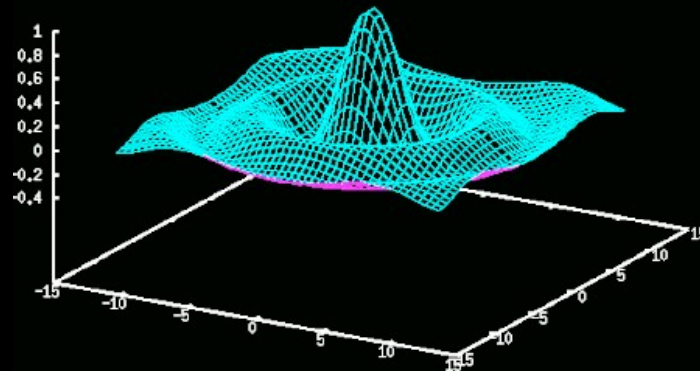

So we will use Matlab to study CA:

Industry standard

Performs operations on entire table at once (no click-and-drag)

Programs look much like pseudocode in textbook

Free, open-source version called Octave

Application: Spreading of Fire

# Initializing the System

“Forest” is an  $n \times n$  grid (lattice) of cells.

Each cell is either empty (0) has a tree (1) or has a burning tree (2).

$n$

$n$

- $probTree$  = probability of tree in cell
- $probBurning$  = probability that the tree is burning

# Cell Initialization Algorithm (Pseudocode)

```
if a random number is less than probTree  
  if another random number is less than probBurning  
    assign 2 to the cell // tree is burning  
  else  
    assign 1 to the cell // tree is not burning  
else  
  assign 0 to the cell // no tree
```

# Cell Initialization (Matlab)

```
grid = zeros(n); % N x N grid of zeros
```

```
rand1 = rand(n); % N x N random in [0,1)
```

```
rand2 = rand(n);
```

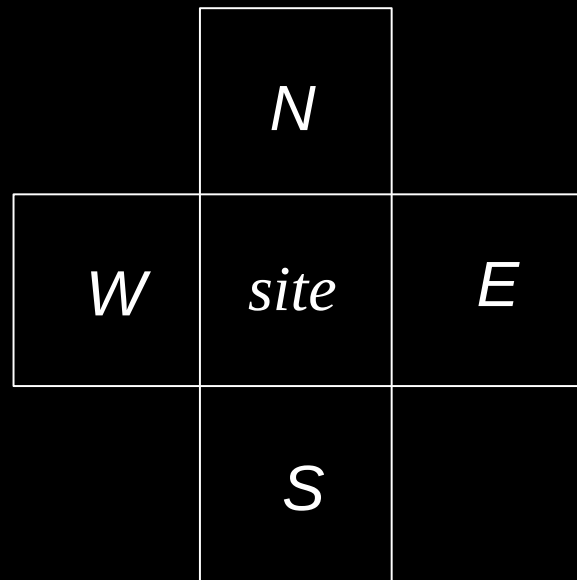

```
grid(rand1 < probTree) = 1;
```

```
grid(rand1 < probTree & rand2 < probBurning) = 2;
```

# Updating Rules

We determine a cell's new state at time  $t + 1$  based on its current state (at time  $t$ ) and the state of the neighbors in its **von Neumann neighborhood** (N, S, E, W):

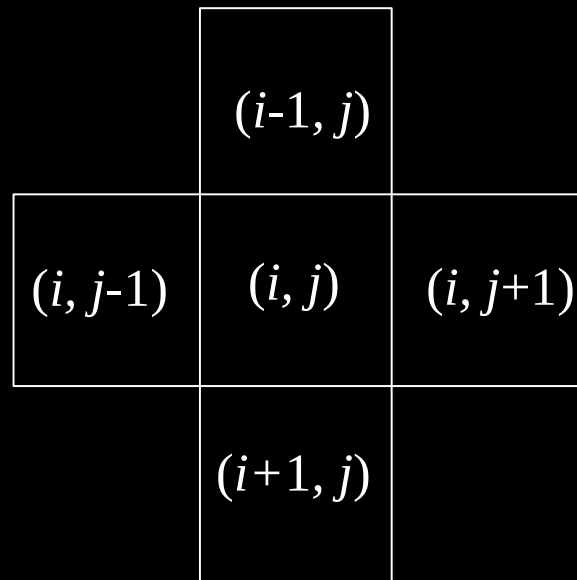

# Updating Rules

- If cell is empty, it stays empty at  $t + 1$
- If a cell has a burning tree, the tree is gone at  $t + 1$
- If a tree is adjacent to a burning tree, it catches fire with a probability  $(1 - probImmune)$
- A tree may also catch fire by being struck by lightning:  $probLightning$

# Applying a Function to Each Grid Point

- $i$  indexes row;  $j$  indexes column

Problem: what to do at boundaries?

# Absorbing Boundary Conditions

Cells beyond perimeter are inactive  
(nothing west of column 1, nothing  
east of column  $n$ , nothing north of  
row 1, nothing south of row  $n$ ).

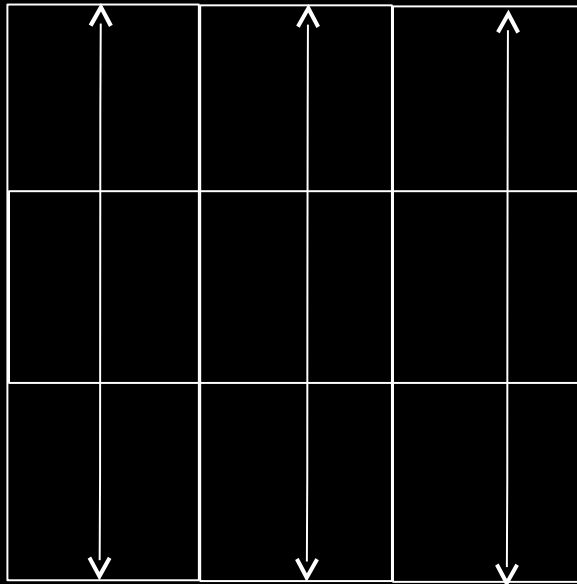

# Periodic Boundary Conditions

Column 1 and column  $n$  are neighbors.

# Periodic Boundary Conditions

Row 1 and row  $n$  are neighbors.

# Periodic Boundary Conditions

This makes the space a **torus**.

# Periodic Boundary Conditions In Matlab

Matlab's `circshift` function does this for us:

```
>> a = [1 2 3; 4 5 6; 7 8 9]
```

```
a =
```

```
    1    2    3  
    4    5    6  
    7    8    9
```

```
>> circshift(a, [0 1]) % W neighbors
```

```
ans =
```

```
    3    1    2  
    6    4    5  
    9    7    8
```

# Translate Updating Rules to Matlab

- If cell is empty, it stays empty at  $t + 1$

**% no action necessary**

# Translate Updating Rules to Matlab

- If a cell has a burning tree, the tree is gone at  $t + 1$

```
newgrid(oldgrid == 2) = 0;
```

# Translate Updating Rules to Matlab

- If a tree is adjacent to a burning tree, it catches fire with a probability  $(1 - probImmune)$

```
n = length(oldgrid); % length of one side
havetree = oldgrid == 1;
susceptible = rand(n) < (1 - probImmune);
nfire = circshift(oldgrid, [1 0]) == 2;
sfire = circshift(oldgrid, [-1 0]) == 2;
efire = circshift(oldgrid, [0 -1]) == 2;
wfire = circshift(oldgrid, [0 1]) == 2;
adjacent = nfire | sfire | efire | wfire;
newgrid(havetree & adjacent & susceptible) = 2;
```

# Translate Updating Rules to Matlab

- A tree may also catch fire by being struck by lightning:  
*probLightning*

```
newgrid(havetree & (rand(n) < probLightning)) = 2;
```
